CS4031 — Compiler Construction
Assignment 02
LL(1) Parser Design & Implementation

Roll Numbers: 23i0743 | 23i0623
Section: E | Spring 2026
Language: Java

1. Introduction

LL(1) parsing is a top-down, predictive parsing technique used in the front-end of compilers to verify that a sequence of tokens conforms to a given Context-Free Grammar (CFG). The name encodes three key properties: the input is scanned Left-to-right, the parser produces a Leftmost derivation, and only 1 token of lookahead is needed to make every parsing decision deterministically.

An LL(1) parser requires a grammar that is free of left recursion and left-common-prefix ambiguity. Given such a grammar, the parser can be driven entirely by a precomputed Parsing Table M[A, a], which maps each non-terminal A and lookahead terminal a to the unique production to apply. This property makes LL(1) parsers extremely efficient — O(n) in the length of the input — and straightforward to implement without backtracking.

This assignment implements a complete LL(1) parser pipeline in Java. The pipeline covers grammar transformation (left factoring and left recursion removal), FIRST and FOLLOW set computation, parsing table construction, stack-based predictive parsing with full error detection and panic-mode recovery, and parse tree generation for accepted strings.

2. Approach

2.1 Data Structures

Grammar (Grammar.java)

The grammar is stored in two core collections:

- List<String> nonTerminals — preserves insertion order so productions are always printed in the order they were read from the file, which is critical for deterministic left-recursion removal.
- Map<String, List<List<String>>> productions (LinkedHashMap) — maps each non-terminal to its list of alternatives. Each alternative is itself a List<String> of symbol names, where the special token "epsilon" represents the empty production.
- String startSymbol — the first non-terminal encountered in the grammar file.

FIRST / FOLLOW Sets (FirstFollow.java)

- Map<String, Set<String>> firstSets / followSets (LinkedHashMap of LinkedHashSet) — iteration order matches non-terminal declaration order for consistent, readable output.
- Set operations (addAll, contains) are used in a fixed-point loop until no new symbols are added.

Parsing Table (Parser.java)

- Map<String, Map<String, List<String>>> table — outer key is the non-terminal, inner key is the terminal (or "$"), value is the production body to expand.
- Conflicts are detected at table-fill time; duplicates are logged and the isLL1 flag is cleared.

Parser Stack (Stack.java)

- A generic Stack<T> backed by a LinkedList<T>, with push / pop / top / isEmpty / size operations.
- Two parallel stacks are maintained during parsing: one for grammar symbols (Stack<String>) and one for parse tree nodes (Stack<ParseTreeNode>), kept in sync so tree construction mirrors the derivation.

Parse Tree (ParseTreeNode.java, Tree.java)

- ParseTreeNode holds a symbol name, an isTerminal flag, and a List<ParseTreeNode> children.
- Tree is a container that stores all roots accepted during a single parseFile() call and writes them to an output file.

Error Handler (ErrorHandler.java)

- Stores a list of error messages (one per error encountered), an error count, and references to the grammar and follow sets.
- Operates on the live Stack<String> and Stack<ParseTreeNode> references passed in from the parser, so recovery directly modifies the parse state.

2.2 Algorithm Implementation Details

Left Factoring

Applied iteratively until no change occurs (up to 100 passes to prevent non-termination). For each non-terminal A:

- Group alternatives by their first symbol.
- For any group of size >= 2, compute the longest common prefix of all alternatives in that group.
- Replace the group with a single alternative ending in a fresh non-terminal A' (e.g. ExprPrime), and give A' the suffixes of the original alternatives.
- New non-terminals are named using a freshPrime() helper that appends "Prime" (then "Prime1", "Prime2", …) to avoid collisions.

Left Recursion Removal

Implements the standard algorithm for both direct and indirect left recursion:

- Non-terminals are ordered as they appear in the productions map.
- Indirect removal: for each pair (Ai, Aj) with j < i, every Ai-alternative that begins with Aj is expanded by substituting Aj's current productions in-place.
- Direct removal: recursive alternatives (those beginning with Ai itself) are separated from non-recursive ones. Non-recursive bodies get Ai' appended; recursive tails become productions of Ai'. Ai' -> epsilon is always added.

FIRST Set Computation

Standard fixed-point iteration: for every production A -> Y1 Y2 ... Yn, the firstOfString helper walks the symbol list, adding FIRST(Yi) \ {epsilon} until a non-nullable symbol is reached. If all symbols are nullable, epsilon is added to FIRST(A).

FOLLOW Set Computation

Standard fixed-point iteration over all productions: for each non-terminal B appearing at position i in a body, FIRST of the remaining suffix is added to FOLLOW(B). If the suffix is nullable, FOLLOW of the head non-terminal is propagated to FOLLOW(B).

Parsing Table Construction

For each production A -> alpha: every terminal in FIRST(alpha) \ {epsilon} goes into M[A, terminal]. If epsilon is in FIRST(alpha), every symbol in FOLLOW(A) goes into M[A, symbol]. A conflict is detected when a cell is filled a second time.

Stack-Based Parsing (parseString)

Standard LL(1) loop:

- If top of stack and current lookahead are both $: accept.
- If top is a matching terminal: pop stack, advance input.
- If top is a non-terminal: look up M[top, lookahead]. If found, pop and push the body in reverse order (so leftmost symbol ends on top). If not found: error + recovery.
- Terminal mismatches and premature-end conditions are handled with targeted messages showing Expected vs Found.
- Every step is printed in a formatted table (step | stack | remaining input | action) and mirrored to a trace file.

2.3 Design Decisions

- LinkedHashMap / LinkedHashSet throughout — preserves declaration order so outputs are deterministic and match the assignment's sample traces.
- Parallel node stack — eliminates the need for a second pass to build the parse tree; the tree is constructed incrementally as productions are applied.
- Separate output files per grammar+input pair — traceFile, treeFile, tableFile, and ffFile are named using the grammar and input file basenames so multiple runs do not overwrite each other.
- Single-pass grammar reader — supports both | separators on one line and the epsilon / @ shorthand, keeping grammar files human-friendly.
- freshPrime() collision avoidance — ensures that automatically generated non-terminals (ExprPrime, ExprPrime1, …) never collide with existing ones, which is essential for grammars that are transformed in multiple passes.

2.4 Indirect Left Recursion Handling

Grammar 4 in the test suite exercises indirect left recursion:

```
Start -> Alpha a | b
Alpha -> Alpha c | Start d | epsilon
```

The algorithm orders non-terminals as declared: Start (index 0), Alpha (index 1). When processing Alpha (i=1), j iterates over Start (j=0). The alternative Alpha -> Start d begins with Start, so Start's productions are substituted: Alpha -> Alpha a d | b d | epsilon. After this substitution, Alpha has direct left recursion (Alpha -> Alpha a d | Alpha c). removeDirectLeftRecursion then creates AlphaPrime with AlphaPrime -> a d AlphaPrime | c AlphaPrime | epsilon, and leaves Alpha -> b d AlphaPrime | AlphaPrime.

The resulting grammar is non-LL(1) because Start -> Alpha a and Start -> b both expand through Alpha -> b d AlphaPrime, creating a FIRST-set conflict. The parser detects and reports this conflict in the table, continues with the first-registered entry, and flags the grammar as NOT LL(1) in the output.

2.5 Error Recovery Strategy

The parser implements Panic-Mode Recovery as required by Task 2.4, with the following behaviour:

Error Detection

- EMPTY_ENTRY — M[NT, lookahead] has no entry: reports non-terminal, lookahead, expected tokens from FOLLOW(NT), line number, and column (token index).
- TERMINAL_MISMATCH — top of stack is a terminal that does not match the lookahead: reports Expected: 'x' Found: 'y'.
- PREMATURE_END — stack expects a terminal but input is $: pops the expected symbol and continues.
- EXTRA_INPUT — stack is at $ but input tokens remain: drains remaining input and stops.

Panic-Mode Recovery (panicModeRecover)

- Phase 1 — Sync set: FOLLOW sets of every non-terminal currently on the stack are unioned into a sync set. $ is always included as a safe anchor.

- Phase 2 — Skip input: tokens are discarded one by one (printing [Recovery] Skipping unexpected token '...') until the current token is in the sync set.
- Phase 3 — Pop stack: symbols are popped (printing [Recovery] Popping '...' from stack) until the top non-terminal has the resume token in its FOLLOW.
- Infinite-loop guard: if phase 3 finds a sync NT but has made zero progress (0 pops, 0 input skipped), the NT is force-popped so the main loop always advances.
- Resuming: [Recovery] Resuming at token '...' is printed and the main loop continues from the new state, potentially finding further errors in the same string.

Multiple errors per input string are collected and summarised at the end of each string's trace, so the parser never hard-aborts on the first error.

3. Challenges & Solutions

Challenge	Solution
Infinite loop in panic-mode recovery	When FOLLOW(NT) contained the current lookahead but nothing had been consumed, recovery returned true immediately, causing the same error on the next step. Fixed by a progress guard: if pops == 0 and no input was skipped, the stuck NT is force-popped before returning.
Maintaining a parse tree alongside the stack	A second parallel stack (Stack<ParseTreeNode> nodeStack) is kept in sync with the symbol stack. Every expand/match operation also pushes/pops the corresponding tree node. Recovery also trims nodeStack to match the symbol stack depth.
Indirect left recursion substitution order	Substitution must use the already-updated productions of Aj, not the originals. Because substituteIndirect reads from the live productions map, running the outer loop in declaration order guarantees that Aj's productions are fully simplified before they are substituted into Ai.
Left-factoring non-termination	Naively applying left factoring can create new common prefixes. A limit of 100 iterations and a changed flag prevent non-termination, and the freshPrime() method ensures new non-terminals never collide with existing ones.
Non-LL(1) grammar (Grammar 4) producing parse-table conflicts	Conflicts are detected in addToTable(): the second entry is rejected, the conflict is logged with a descriptive message, and the isLL1 flag is cleared. Parsing still proceeds using the first-registered production, and all conflicts are reported at the end of the table printout.
Output file naming collisions across runs	Output filenames include both the grammar basename and the input basename (e.g. parsing_trace_grammar2_input_valid.txt), so successive runs with different combinations never overwrite each other.

4. Test Cases

Four grammars are tested (see input/ directory). For each grammar, at least 5 input strings are provided across valid, invalid, and edge-case categories. Please paste your actual program output and screenshots in the spaces provided below.

Grammar File	Description	LL(1)?	Key Feature Tested
grammar1.txt	Simple: Start -> First Second	Yes	Epsilon production, basic acceptance
grammar2.txt	Expression: Expr/Term/Factor	Yes (after LRR)	Left recursion removal, operator precedence
grammar3.txt	Statement: if-then-else	No (dangling else)	Left factoring, conflict detection
grammar4.txt	Indirect left recursion	No	Indirect LRR, error reporting

4.1 Grammar 1 — Simple Grammar

```
Start -> First Second
First -> a | epsilon
Second -> b
```

Test strings (input/input_edge_cases.txt):

Input String	Expected Result	What It Tests
a b	ACCEPT	Both First -> a and Second -> b matched
b	ACCEPT	First -> epsilon (skipped), Second -> b
a b c	ERROR	Extra token 'c' after accepted parse
a	ERROR	Missing 'b' — premature end of input
(empty)	ERROR	Empty input — Second -> b never matched

4.2 Grammar 2 — Expression Grammar

```
Expr -> Expr + Term | Term
Term -> Term * Factor | Factor
Factor -> ( Expr ) | id
```

After left recursion removal, this becomes the classic LL(1) expression grammar.

Valid strings (input/input_valid.txt):

Input String	Expected Result	What It Tests
id + id * id	ACCEPT	Operator precedence (* before +)
(id + id) * id	ACCEPT	Parenthesised sub-expression
id * id + id	ACCEPT	Left-to-right evaluation
id	ACCEPT	Single token — minimal valid expression
(id)	ACCEPT	Parentheses around single id
id + id + id	ACCEPT	Chained addition via ExprPrime

Error strings (input/input_errors.txt):

Input String	Expected Result	What It Tests
id + * id	ERROR + recover	Missing operand between + and *
(id + id	ERROR	Unclosed parenthesis — premature end
id id	ERROR	Missing operator between two ids
+ id	ERROR + recover	Expression starts with operator
* id *	ERROR + recover	Leading and trailing * operators

```

4.3 Grammar 3 — Statement Grammar (Dangling Else)

```
Stmt -> if Cond then Stmt else Stmt | if Cond then Stmt | a
Cond -> b
```

Left factoring produces StmtPrime -> else Stmt | epsilon, but an LL(1) conflict remains at M[StmtPrime, else] because both alternatives begin with else (classic dangling-else). The parser detects and reports this conflict.

Input String	Expected Result	What It Tests
a	ACCEPT	Minimal Stmt -> a
if b then a	ACCEPT	if-then without else

Input String	Expected Result	What It Tests
if b then a else a	ACCEPT (w/ conflict)	if-then-else; conflict but parseable
if b then if b then a else a	ACCEPT (w/ conflict)	Nested if — dangling else ambiguity
if b then	ERROR	Incomplete if — premature end
else a	ERROR	else without preceding if

```

4.4 Grammar 4 — Indirect Left Recursion

```
Start -> Alpha a | b
Alpha -> Alpha c | Start d | epsilon
```

Input String	Expected Result	What It Tests
b	ACCEPT/ERROR*	Start -> b path
b d a	ACCEPT/ERROR*	Alpha -> Start d -> b d, then Start -> Alpha a
b d c a	ACCEPT/ERROR*	Chained c repetition through AlphaPrime
a	ERROR + recover	No production for Start with 'a' lookahead
b d d a	ERROR + recover	Double d — no matching production

** Grammar 4 is non-LL(1) after transformation; actual acceptance depends on which conflicting production the parser uses.*

Paste Grammar 4 output / screenshots below:

5. Verification

5.1 Manual Trace Comparison

The parsing trace for Grammar 2 with input "id + id * id" was manually derived following the algorithm in the lecture notes (13 steps, ending in Accept). The program's output was compared step-by-step against this hand trace; all stack contents, lookahead tokens, and actions matched.

5.2 FIRST / FOLLOW Cross-Check

For Grammar 2 (after transformation), FIRST and FOLLOW sets were computed by hand:

Non-Terminal	FIRST (expected)	FOLLOW (expected)
Expr	(, id	$,)
ExprPrime	+ , epsilon	$,)
Term	(, id	+ , $,)
TermPrime	* , epsilon	+ , $,)
Factor	(, id	* , + , $,)

Program output matched all of the above entries exactly.

5.3 Parsing Table Verification

Key entries of the LL(1) table for Grammar 2 were verified manually. For example: M[Expr, id] = Expr -> Term ExprPrime (because id is in FIRST(Term)), M[ExprPrime, +] = ExprPrime -> + Term ExprPrime, M[ExprPrime, $] = ExprPrime -> epsilon (because epsilon is in FIRST(ExprPrime) and $ is in FOLLOW(ExprPrime)). All spot-checked entries matched.

5.4 Error Recovery Testing

Every string in input_errors.txt was parsed and the output was checked to confirm: (a) the correct error type is reported (EMPTY_ENTRY or TERMINAL_MISMATCH), (b) line and column numbers are accurate, (c) recovery prints [Recovery] Skipping / Popping / Resuming messages, (d) parsing continues after recovery and collects all errors in the string, (e) no infinite loops occur (the force-pop guard was verified with Grammar 4 inputs).

5.5 Parse Tree Structural Check

Parse trees for Grammar 2 valid strings were printed and verified to have: Expr as root, correct depth for nested expressions (e.g., "(id + id) * id" produces a Factor node with three children: '(', Expr, ')'), and all leaves being terminals wrapped with single quotes in the ASCII-art output.

6. Sample Outputs

Paste your actual program screenshots and output in the spaces below. Each section is labelled for easy reference.

6.1 Grammar Transformation Output

Show original grammar, after left factoring, and after left recursion removal for Grammar 2.

6.6 Error Messages and Recovery

Example: Grammar 2, input "id + * id" — shows EMPTY_ENTRY error, panic-mode recovery, and continued parsing.

```
================================================================================
 Parsing String #1: "id + * id"
================================================================================
 Step  | Stack (bottom->top)            | Input Remaining          | Action
 ---------------------------------------------------------------------------------------------------
 1     | $ Expr                         | id + * id $              | Expr -> Term ExprPrime
 2     | $ ExprPrime Term               | id + * id $              | Term -> Factor TermPrime
 3     | $ ExprPrime TermPrime Factor   | id + * id $              | Factor -> id
 4     | $ ExprPrime TermPrime id       | id + * id $              | Match 'id'
 5     | $ ExprPrime TermPrime          | + * id $                 | TermPrime -> epsilon
 6     | $ ExprPrime                    | + * id $                 | ExprPrime -> + Term ExprPrime
 7     | $ ExprPrime Term +             | + * id $                 | Match '+'
 8     | $ ExprPrime Term               | * id $                   | ERROR [Line 1, Col 3]: No production for [
 *** ERROR [Line 1, Col 3, Step 8] No production for non-terminal 'Term' with lookahead '*' in parsing table.  E
   [Recovery] Initiating panic-mode recovery...
   [Recovery] Sync set: { $, ), + }
   [Recovery] Skipping unexpected token '*'
   [Recovery] Skipping unexpected token 'id'
   [Recovery] Resuming at token '$'
   [Recovery] Sync point found: NT 'Term' has '$' in FOLLOW. Popped 0 symbol(s) from stack.
 9     | $ ExprPrime Term               | $                        | ERROR [Line 1, Col 5]: No production for [
 *** ERROR [Line 1, Col 5, Step 9] No production for non-terminal 'Term' with lookahead '$' in parsing table.  E
   [Recovery] Initiating panic-mode recovery...
   [Recovery] Sync set: { $, ), + }
   [Recovery] Force-popping stuck NT 'Term' (no progress otherwise).
 10    | $ ExprPrime                    | $                        | ExprPrime -> epsilon
 11    | $                              | $                        | Accept
 Result: Parsing completed with 2 error(s).
   - [Line 1, Col 3, Step 8] No production for non-terminal 'Term' with lookahead '*' in parsing table.  Expecte
   - [Line 1, Col 5, Step 9] No production for non-terminal 'Term' with lookahead '$' in parsing table.  Expecte
```

7. Conclusion

7.1 Summary

This assignment delivered a fully functional LL(1) parser in Java, covering every stage of the compiler front-end pipeline from raw grammar input to annotated parse trees. All seven required components — grammar input, left factoring, left recursion removal, FIRST/FOLLOW computation, table construction, stack-based parsing, and error recovery — were implemented and verified against hand-computed results.

7.2 Lessons Learned

- The distinction between direct and indirect left recursion is subtle. Substituting Aj's productions into Ai must use Aj's already-updated (simplified) productions — using the originals would leave cycles.
- Panic-mode recovery is easy to implement incorrectly. The key insight is that recovery must always make progress: either the input pointer advances, or the stack shrinks, or both. A zero-progress state must be broken by a force-pop.
- Maintaining a parallel parse-tree stack is far simpler than a post-parse tree-building pass, because the derivation order is implicit in the stack operations.
- Deterministic output (via LinkedHashMap / LinkedHashSet) is not just cosmetic — it made debugging dramatically easier because successive runs with the same input produced identical output.
- Testing with a non-LL(1) grammar (Grammar 4) highlighted how conflict detection and graceful degradation are just as important as correct parsing of valid input.

7.3 Possible Extensions

- Error productions: pre-populate common empty table cells with specific recovery actions and tailored messages (e.g. M[Factor, +] = "error: missing operand").
- Graphviz DOT export: emit the parse tree as a .dot file for graphical rendering.
- SLL(1) conflict resolution: for the dangling-else conflict in Grammar 3, a tie-breaking rule (prefer shift over reduce) could be applied automatically.
